Overview

GreyNoise Platform

GreyNoise is a threat intelligence platform that monitors internet wide scanning, crawling, and exploitation activity across the Internet. Its core value is helping security teams filter out the “noise” - that is, mass scanning, benign crawlers, or otherwise common scan activity that often triggers alerts but is not necessarily targeting your assets - so you can focus on truly malicious or targeted activity.

Google SecOps

Google SecOps is a modern, cloud-native SecOps platform that empowers security teams to better defend against today's and tomorrow's threats. By combining Google's hyper-scale infrastructure, unparalleled visibility, and understanding of cyber adversaries, Google SecOps provides curated outcomes that proactively uncover the latest threats in near real-time, and enable security teams to detect, investigate and respond with speed and precision.

Google SecOps Integration for GreyNoise

The SOAR component extends GreyNoise capabilities with powerful automation and response features. It enables bi-directional synchronization of threat intelligence between GreyNoise and Google SecOps, allowing security teams to operationalize threat data effectively. Through automated playbooks, security teams can implement rapid response actions such as blocking malicious indicators, updating threat intelligence, and managing security incidents at scale.

Release Notes

V7.0

- Upgraded GreyNoise SDK to version 3.0.1
- Added [Get CVE Details](#) action to retrieve CVE information from GreyNoise
- Added the following parameters to the [Execute GNQL Query](#) action:
 - Exclude Raw
 - Quick
- Updated parameters in [IP Timeline Lookup](#) action:
 - Removed: Limit
 - Added: Field
 - Added: Granularity
- Removed the following actions:
 - Community IP Lookup (use [IP Lookup](#) action instead)
 - RIOT IP Lookup (Deprecated use [IP Lookup](#) action instead)
 - IP Similarity Lookup (Deprecated)

App Installation & Configuration

Pre-Requisites

Google SecOps

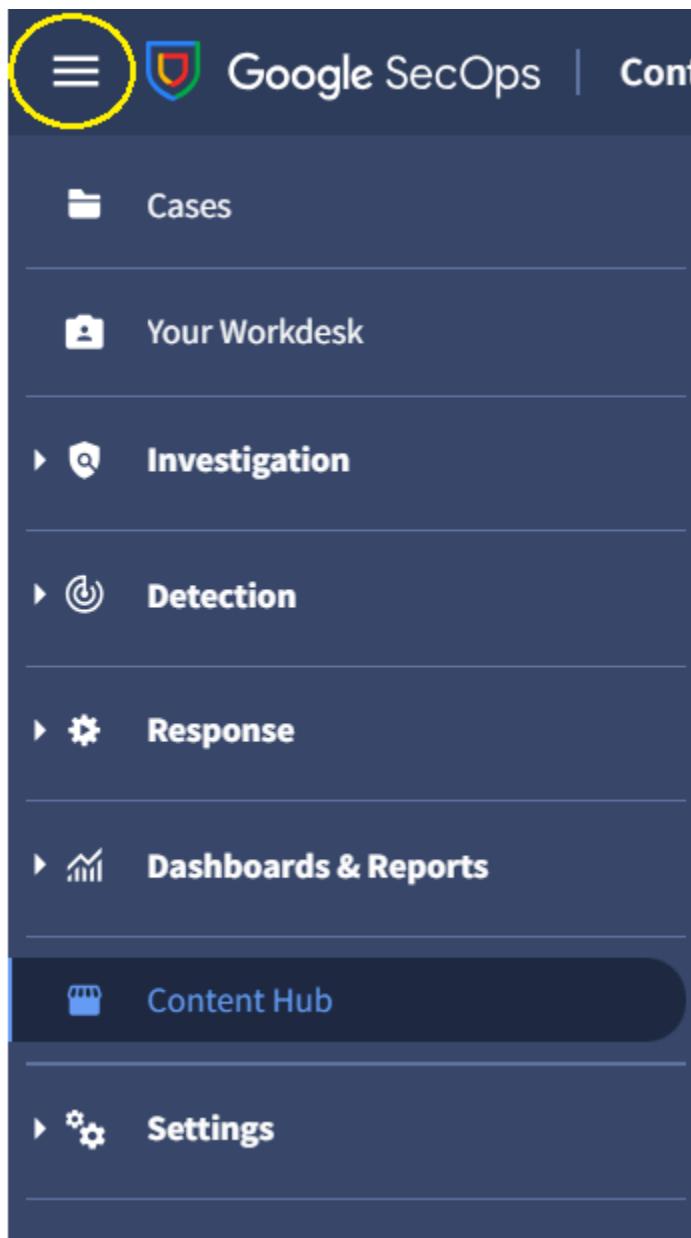

- A Google SecOps SOAR Instance with an Admin role user.

GreyNoise

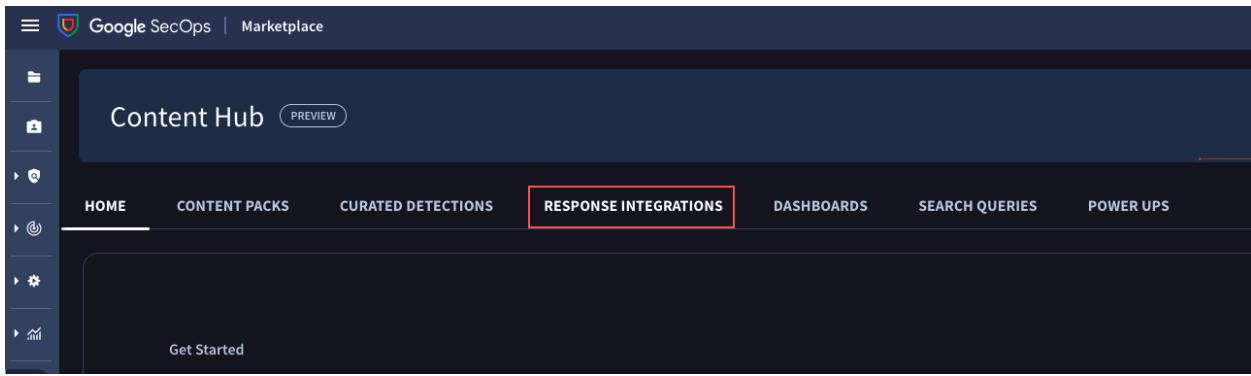

- GreyNoise Intelligence platform (API Key).

Installing the Integration

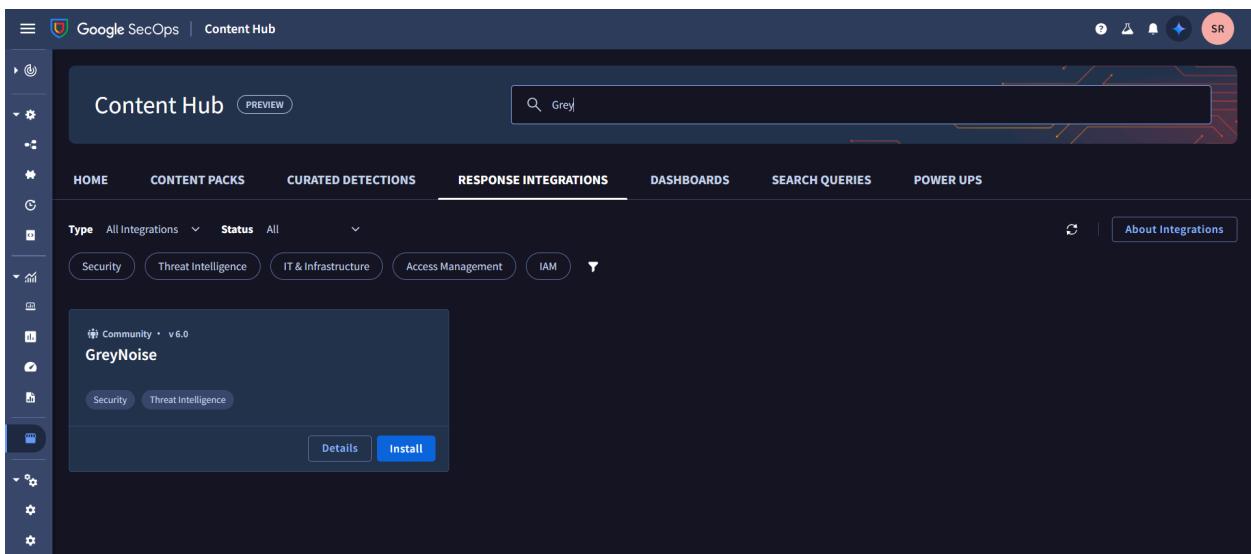

1. Log in to the Google SecOps SOAR Platform.
2. From the Sidebar, click on the **Content Hub** section

3. In the Content Hub, click on the Response Integrations tab.

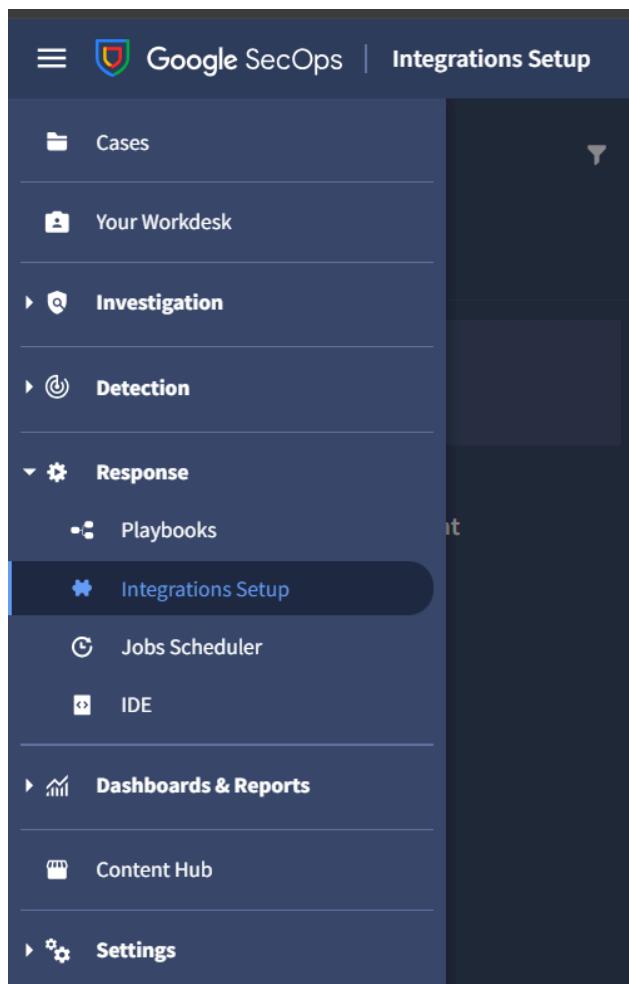

4. From the **Response Integrations** tab, search for **GreyNoise**.

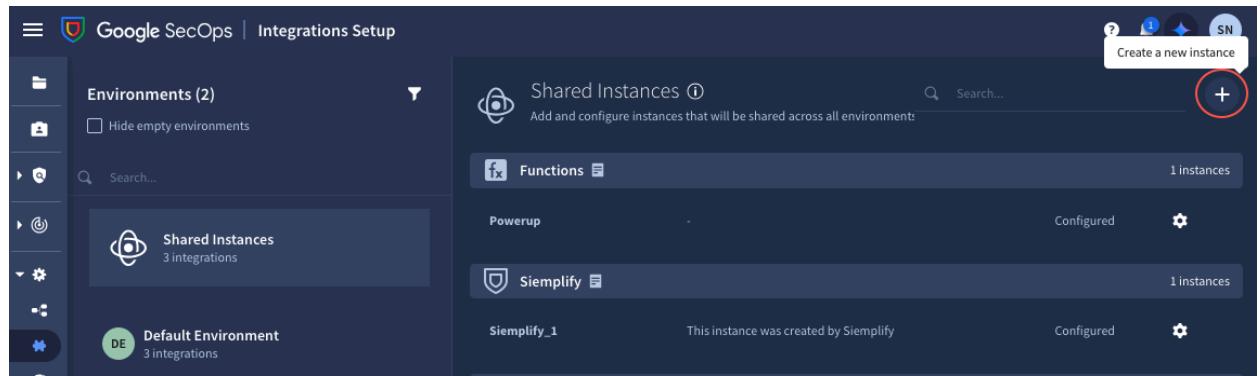

5. Click the **Install** button to install the integration.

Configuration

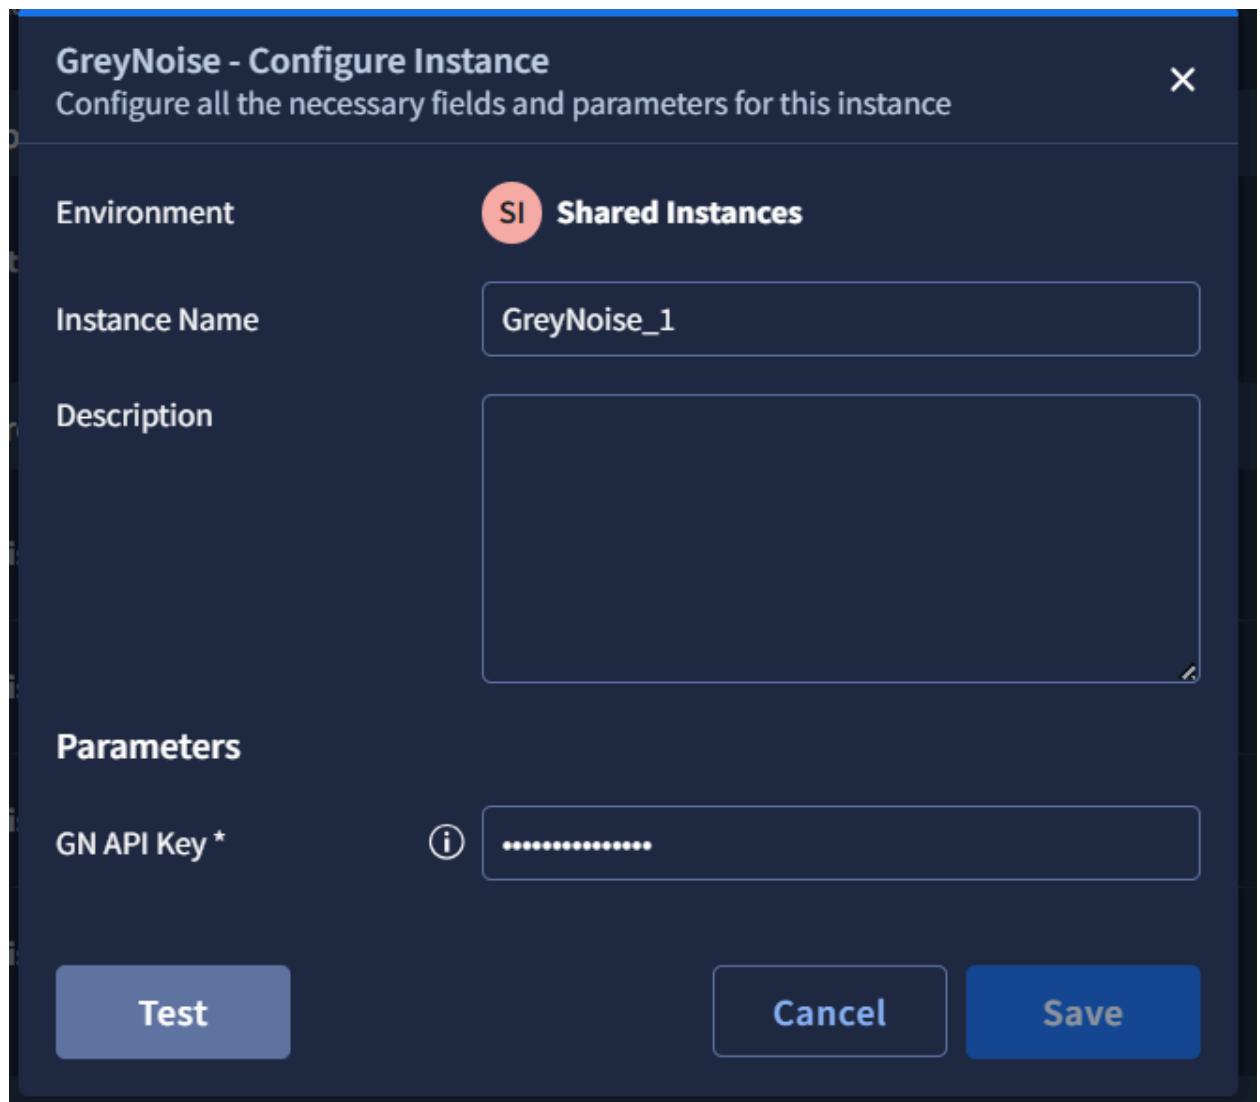

1. Once the integration has been installed successfully, the user needs to configure it to use the actions provided by the integration. These actions can be run manually from a case or can be used in playbooks.
2. To configure the integration, users can navigate to **Response > Integrations Setup**.

3. The integration can be configured in any of the desired environments. The integration actions can be used for playbooks and cases belonging to the environment in which the integration is configured.
4. Click on the **Plus (+)** button to configure the integration for the desired environment.

5. Search for GreyNoise integration and select it. Click **Save**.
6. The instance of integration will be saved. However, in the next pop-up, users must add the necessary configuration parameters to use the actions.

Field name	Description	Default value	Required	Type
GN API Key	GreyNoise API Key	-	True	String

7. After adding the valid configuration parameters, click on the **Save** button to save the configurations. This is required to access the GreyNoise APIs used in the actions.
8. After saving the configurations, the user can validate them using the **Test** button
 - a. A green tick mark appears if the credentials provided are valid.

- b. If invalid credentials are provided or any internal issue is faced, a red cross mark on the right side of the Test button will appear. The full error message can be displayed by clicking the red cross button.

```
----- Main - Param Init -----  
Reading configuration from Server -----  
---- Main - Started ----- Unable to  
auth, please check API Key Connection to  
API failed, performing action GreyNoise -  
Ping ----- Main - Finished -----  
--- Status: 2 result_value: False Output  
Message: Failed to connect to the GreyNoise  
server! Unable to auth, please check API  
Key
```

Note:

- After making any changes in the configuration parameters, the user needs to save them before testing again using the Test button.
- When updating the credentials, the user must delete the entire Password from the input first before adding the updated Password.

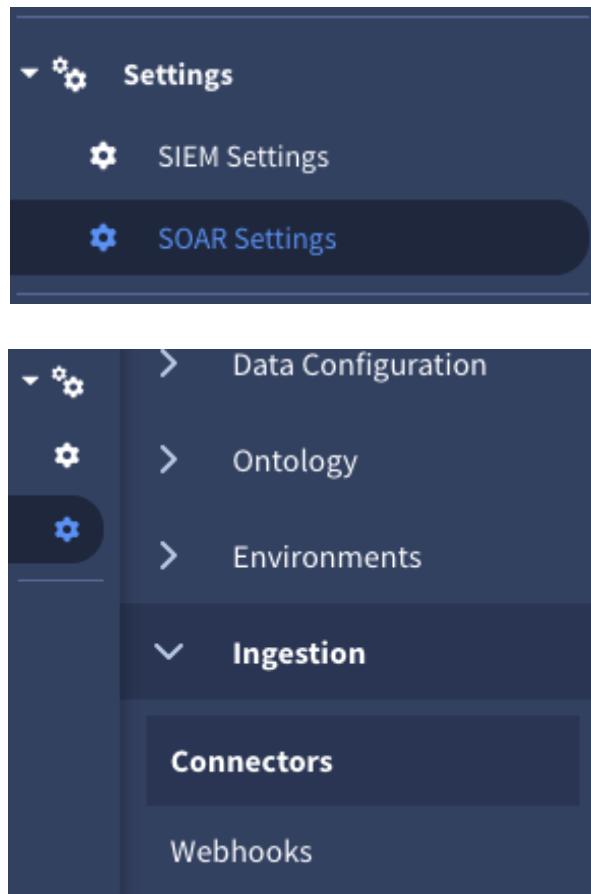

More information about configuring integrations in Google SecOps can be found [here](#).

GNQL Connector

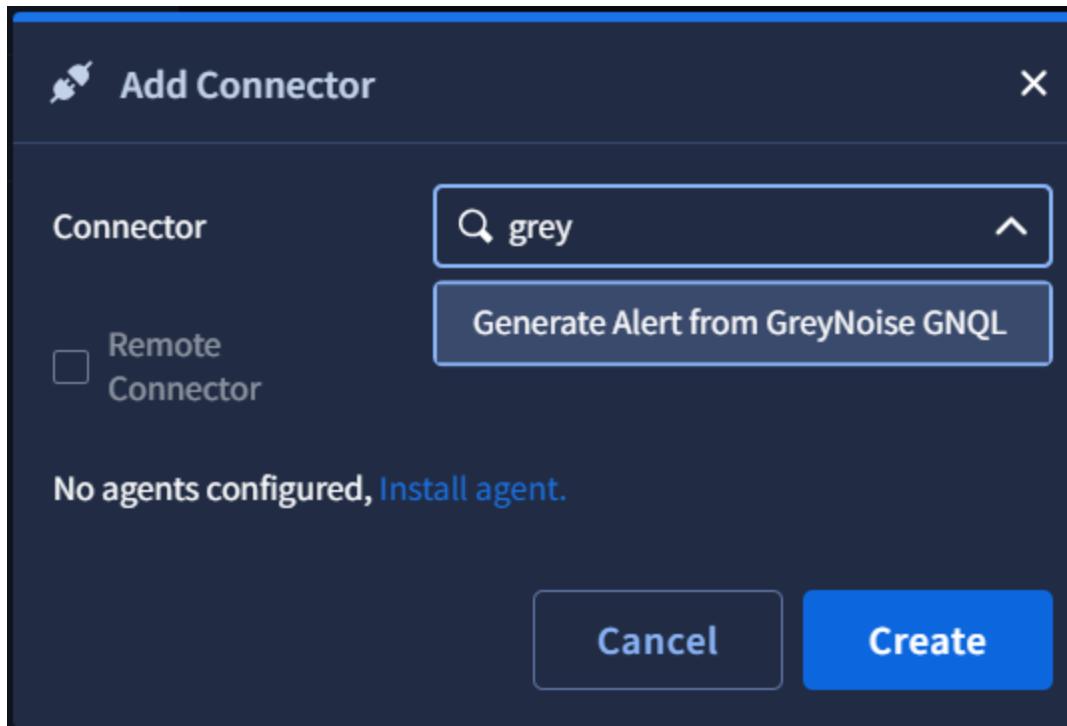

The connector automates the process of querying GreyNoise GNQL API to retrieve threat intelligence data and generate corresponding alerts in Google SecOps. It helps identify scanning or malicious IPs observed by GreyNoise and transforms those findings into actionable alerts.

Connector Configuration

1. Go to **SOAR Settings > Ingestion > Connectors**.

2. Select the + icon to add a new connector and then select Generate Alert from GreyNoise GNQL Connector from the dropdown and then Create.

3. Complete the parameters configuration, enable and **Save** the connector.

Field name	Description	Default value	Required	Type
API Key	API Token	N/A	True	Password

Query	GNQL query	last_seen:1d	True	String
Max Results	The number of max results to fetch.	100	False	Integer

Actions

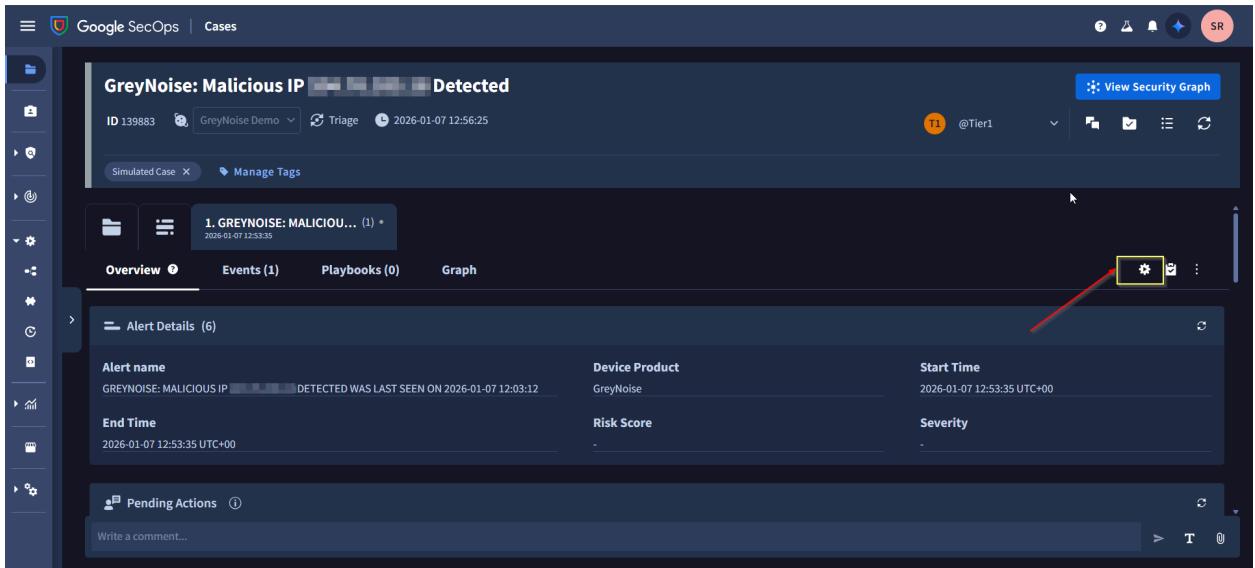

This integration implements investigative and generic actions for the GreyNoise platform on the Google SecOps SOAR Platform. It enables end-users to implement comprehensive network security use cases on the GreyNoise Platform through the below available actions.

1. **Test Connectivity (ping):** Tests the connectivity of the Google SecOps SOAR server to the GreyNoise platform by validating the provided GreyNoise API credentials.
2. **Quick IP Lookup:** Performs a rapid check of an IP address using the GreyNoise SDK to determine if it is associated with internet scanning activity or a known business service. Returns trust level, classification, scanner, and business service fields.
3. **Execute GNQL Query:** Executes a GreyNoise Query Language (GNQL) query, returning a list of IP addresses and metadata that match the query criteria. Supports pagination, partial field omission, and error handling for invalid keys and queries.
4. **IP Lookup:** Performs a comprehensive lookup for one or more IP addresses using the GreyNoise SDK, returning enriched intelligence such as classification, noise/RIOT status, actor, tags, CVEs, behavioral flags, business service information, scanner status, and more.
5. **IP Timeline Lookup:** Retrieves a historical activity timeline for a specified IP address, showing changes over a selected field (e.g., classification, ports) with configurable day/hour granularity using GreyNoise data.
6. **Get CVE Details:** Fetches detailed information about a specific CVE, providing vulnerability info, CVSS/EPSS scores, exploitation stats, threat actor activity, exploitation timeline, and observed related IP activity from GreyNoise sensors.

Invoking Actions

Invoke Action Manually (from Case)

1. Navigate to the Case **Overview** tab of the case on which the action needs to be performed.
2. In the selected case, click Manual Action ('gear' icon) located on the right side under the Case Top Bar. The Manual Action dialog box appears.

3. Select the required action: **GreyNoise** > **[Action Name]**. Make sure to fill in the required information.
4. Once the information is added, click on the **Execute** button.
5. Once the action is successfully executed, the result (success or failure) will be displayed on the Case wall.
6. The result contains different JSON output and insights based on different actions.

Invoke Action Automatically (from Playbook/Block)

Actions can be added as a step in a playbook. This action will be run when the playbook is executed. Playbooks, in turn, can be triggered on cases and alerts based on the conditions determined by the user.

To add an action as a part of the playbook, follow these steps:

1. Navigate to **Response > Playbooks**
2. Select any existing playbook or create a new one.
3. Click on the **+ Open Step Selection** button, and navigate to the Actions tab.
4. Under GreyNoise integration, all the actions available in the integration would be visible. Simply, drag and drop the action required to the playbook step.
5. The action should now be added to the playbook. Make sure to configure the input parameters (if applicable) for the action.

Playbooks

As part of the GreyNoise Integration, we created **Five** playbooks and a block to help the user get started. Users can use and refer to the sample playbook provided in [Github Repo](#)

The Playbooks & block included are:

1. CVE-Based Network Containment Orchestrator - GreyNoise
2. Noise Elimination - GreyNoise
3. Network Containment Based on GreyNoise IP Feed - GreyNoise
4. Dynamic Case Naming from Webhook - GreyNoise
5. Network Containment Block - GreyNoise

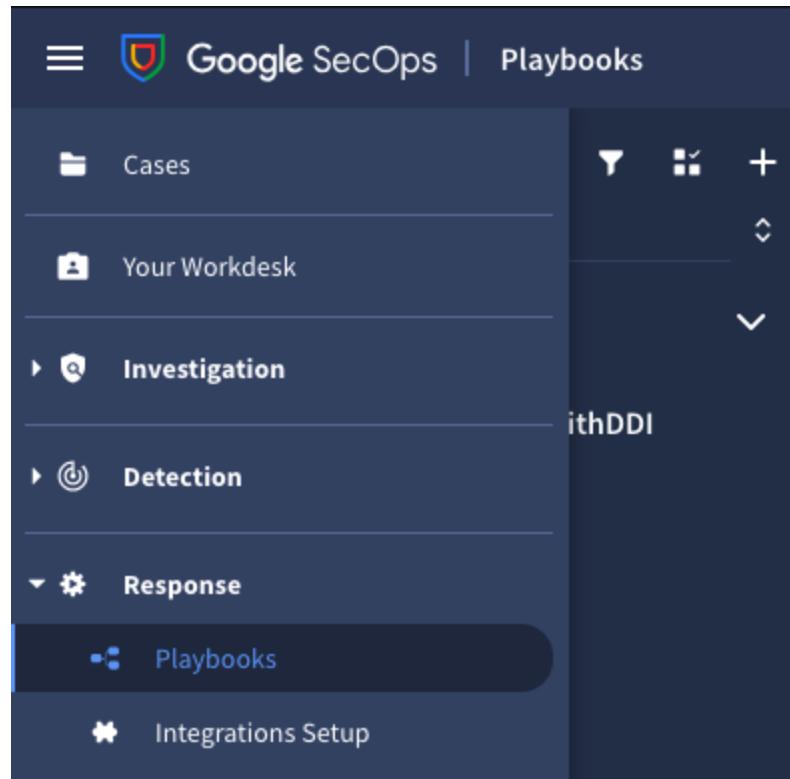

Notes:

- .zip file for every playbook contains the playbook along with all the blocks used in that playbook.
- Each playbook requires a trigger, which decides when the playbook would be run. Users can update the Trigger conditions based on the requirements.
- As the trigger of every playbook is set to run on all ingested alerts into SecOps instance, the imported playbooks are disabled by default. Imported Playbooks and a block can be found in the **Imported Playbooks** folder. These playbooks and blocks can be moved to any other folder of User's choice. Users can easily enable any playbook by simply clicking on the toggle button beside the playbook name. ([Reference](#))

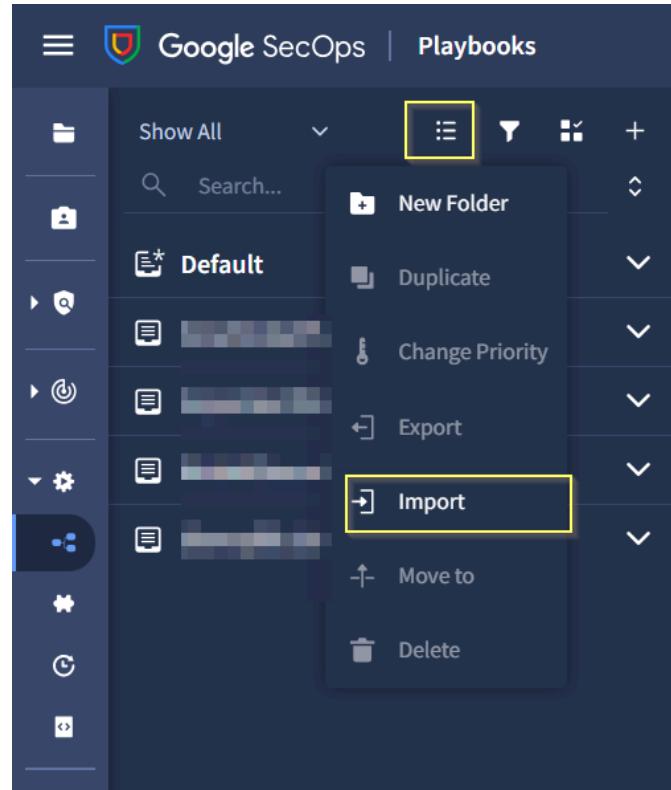

Import Playbooks

To import a playbook into any SecOps instance follow the below steps:

1. Download the .zip file of the playbook that needs to be imported from [Playbooks](#) . This file would also contain all the blocks that are used in the playbook.
2. Navigate to **Response > Playbooks**.

3. Click on the **three dots** icon at the top of the Playbooks, and then click on **Import**.

4. Select the .zip file downloaded earlier.

The playbooks stored in the file would be imported. We can access these under the **Imported Playbooks** folder. These playbooks and blocks can be moved to any other folder of our choice.

You can also download the [All GreyNoise Playbooks Bundle](#) which includes all the GreyNoise playbooks and blocks.

Note: Before using any playbook with an alert, review its default settings (triggers, action parameters, etc.) to ensure they align with your needs

Webhook

The GreyNoise for Google SecOps SOAR Integration will support ingestion of Alerts and Feeds data via webhook delivery. Webhooks will allow GreyNoise events to be delivered directly into Google SecOps SOAR.

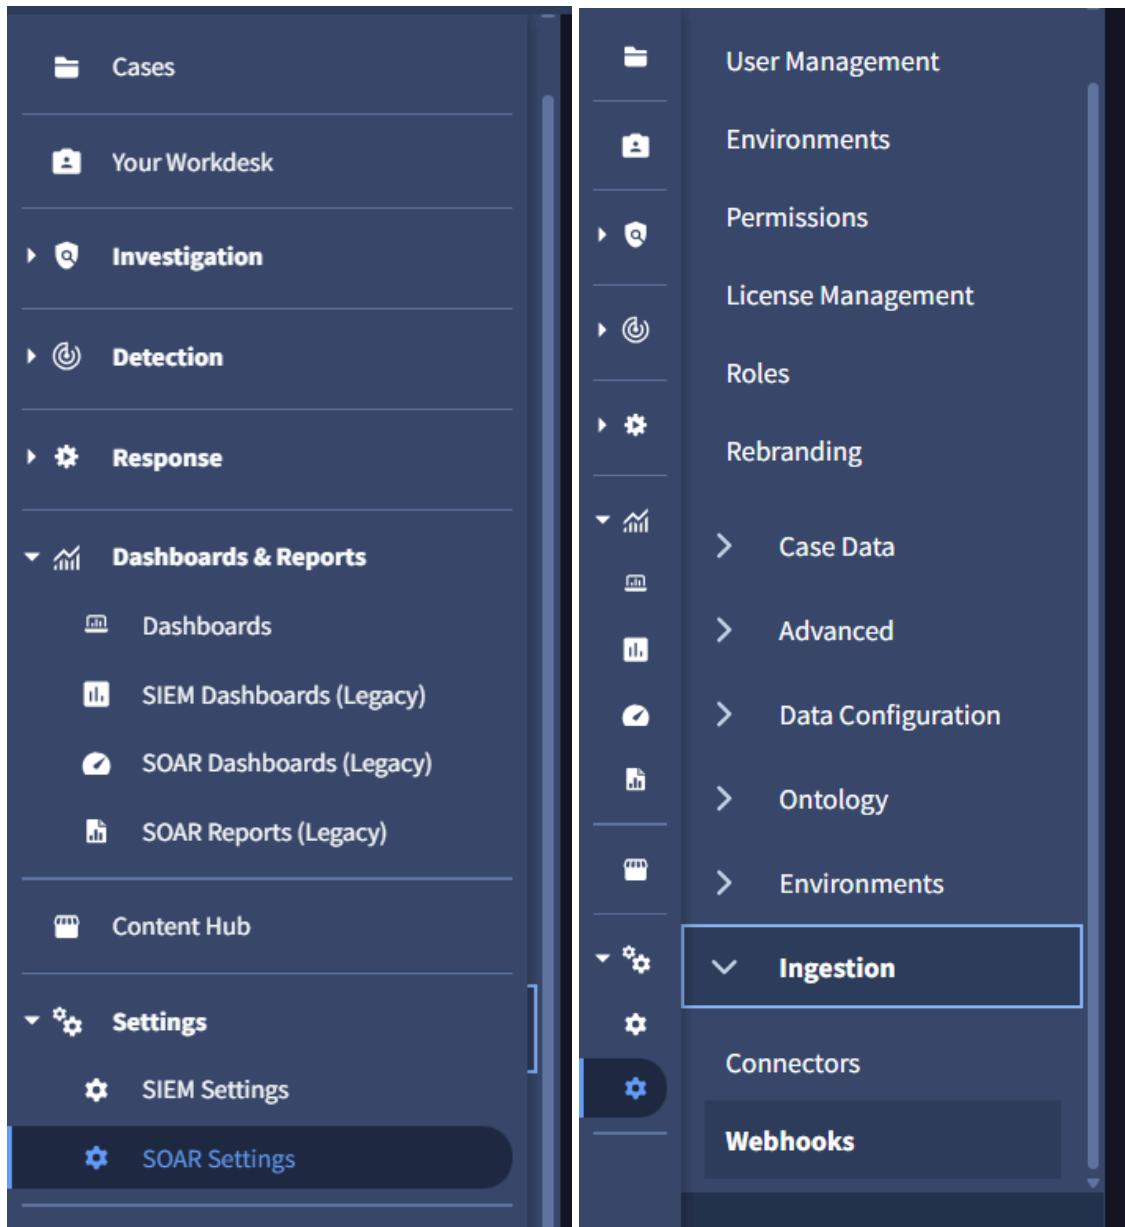

To ingest the Alerts and Feed data using the Webhook we need to create 3 webhooks to support the different schemas.

1. **GreyNoise Alert Webhook:** Supports all the Alert Schemas ([IP](#), [CVE](#), [TAGS](#), [GNQL Query](#))
2. **GreyNoise IP Change Webhook:** Supports only the [IP Classification Change Feed](#).
3. **GreyNoise CVE Change Webhook:** Supports the [CVE Spike Activity](#) and [CVE Status Change](#) Feed.

Note: Based on the User's requirement he needs to configure the relevant webhook in the Google SecOps.

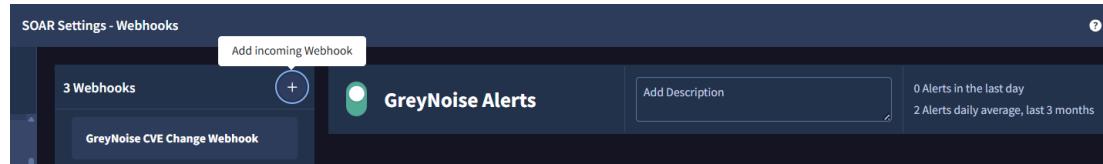

Webhook Configuration

1. **Access Google SecOps SOAR:**
 - Log in to the Google SecOps SOAR UI as an admin.
 - Navigate to **SOAR Settings** → **Ingestion** → **Webhooks**.

2. Add Incoming Webhook:

- Click **Add Incoming Webhook (+)**.
- Enter a Name for this webhook (e.g., GreyNoise Alert Webhook).
- Choose the appropriate Environment. (where user wants to ingest the alerts)
- Click **Save**.

A modal dialog titled "Create new Webhook" is displayed. It contains three fields: "Name *" with the value "GreyNoise IP Change Webhook", "Environment *" with a dropdown menu showing "GreyNoise Test", and a "Description" field which is empty. At the bottom right are two buttons: "Cancel" and a blue "Save" button.

3. Generate Webhook URL:

- After saving, the platform will generate a webhook URL.
- Important:** Copy the webhook URL immediately — it cannot be retrieved again once you leave the page. You will need this URL for configuring your source (e.g., GreyNoise).

The screenshot shows the configuration interface for a 'GreyNoise IP Change W...' webhook. At the top, there's a header with a logo, the title, an 'Add Description' input field, alert statistics (0 alerts in last day, 0 alerts daily average over 3 months), and a 'Save' button. Below the header, there are two tabs: 'Parameters' (selected) and 'Testing'. Under 'Parameters', there's a 'Copy to clipboard' button. The 'Webhook URL' field contains a long URL starting with 'https://crestdatasys.siemplify-soar.com/webhooks/9b76f320-7...'. The 'Environment' dropdown is set to 'GreyNoise Test'. In the 'Data Mapping' section, there's a note to 'Start mapping data to Google SecOps's alert fields.' and a 'Upload JSON sample' button. On the left, a sidebar lists 'Google SecOps alert fields' with 'Mandatory' selected. The listed fields are: TicketId, SourceSystemName, Name, DeviceVendor, RuleGenerator, and StartTime. A message at the bottom of the mapping area says 'No Google SecOps field was selected' and 'Select field from Google SecOps alert fields on the left & data source on the top to start mapping.'

4. Map the Alert Fields:

- In the Data Mapping section, click **Upload JSON sample**.
- Upload a representative webhook payload from your alert source (e.g., a sample GreyNoise webhook JSON).
- Use the Expression Builder to map each field in SOAR to a JSON path or literal value.
- After mapping, use the **Run** button in the Expression Builder to preview output and confirm proper mapping (green checkmark indicates success).

The screenshot shows the 'SOAR Settings - Webhooks' interface. On the left, there are two webhook configurations: 'GreyNoise Alert Webhook' and 'GreyNoise IP Change Webhook'. The right side is the 'Data Mapping' section. It includes a 'Data Mapping' header, a 'Start mapping data to Google SecOps's alert fields.' message, and a 'Upload JSON sample' button. The 'Webhook fields' section contains a list of mapped fields: event_type (IP Classification Change), ip (47.239.198.223), new_state [1], old_state [1], and timestamp (2025-04-30T08:10:00Z). The 'Select function' sidebar lists various functions like first, last, min, max, filter, dateFormat, count, orderBy, toLower, and toUpper. Below the mapping area is an 'Expression builder' input field containing '| "ip"' and a 'Run' button. The 'Results' section shows the value '47.239.198.223'.

Notes:

- The static values will not be visible in the preview output. However, they will be saved and will be populated during the ingestion process.
- We have temporarily mapped Alert Priority to the classification field even though Priority is an enum; this mapping will not correctly determine priority due to webhook expression builder limitations. The current webhook mapping UI does not support nested if-else logic to map multiple classification values to priority levels (e.g., "malicious → CRITICAL", "benign → MEDIUM"), as discussed in the [community forum](#).

5. Enable the Webhook:

- Once all necessary fields are mapped, click **Save** and then **Enable** the webhook.

The screenshot shows the 'GreyNoise IP Change W...' configuration page. It features a summary bar with the title 'GreyNoise IP Change W...', a description 'Enable ingestion of GreyNoise feed data IPs into Google SecOps SOAR to track suspicious state changes over time and', and performance metrics '0 Alerts in the last day' and '0 Alerts daily average, last 3 months'. A large blue 'Save' button is at the bottom right.

6. Setup on GreyNoise:

- Follow the instructions from GreyNoise to set up [Alerts](#) and [Feeds](#).

1. Alerts Webhook

1.1. Goal

To enable ingestion of GreyNoise Alert data into Google SecOps SOAR using webhooks.

1.2. Mapping

Field	Mapping Value	Value Type	Description
TicketID	alert.id	Dynamic	Unique identifier for the alert
SourceSystemName	GreyNoise	Static	Identifies the source system
Name	alert.name	Dynamic	Name of the alert
DeviceVendor	GreyNoise	Static	Vendor information
RuleGenerator	GreyNoise-Alert	Static	Static value for consistency
StartTime	timestamp	Dynamic	Time the alert was generated
Reason	alert.creator	Dynamic	Creator of the alert
DeviceProduct	GreyNoise-Alert	Static	Product information
EndTime	timestamp	Dynamic	Time the alert ended
Priority	data.classification	Dynamic	Classification of the alert
EventsList	data first(1)	Dynamic	List of events

			Note: Here we are only considering the first record so it can be easily accessible in the playbook.
EventProduct	GreyNoise	Static	Product information
EventName	alert.name	Dynamic	Name of the event

1.3. Supported Webhook Schemas

IP

```

```

2. Feeds Webhook

2.1. Goal

Enable ingestion of GreyNoise feed data (IPs and CVEs) into Google SecOps SOAR to track observable state changes over time and trigger appropriate playbooks based on updates.

Note: You Need to create two webhooks, one for the IP Classification Change and another for CVEs (Spike and Status Change)

2.2. Mapping

Mapping for CVE Status Change and CVE Activity Spike Webhook

Field	Mapping Value	Value Type	Description
TicketID	cve	Dynamic	Unique identifier for the CVE event
SourceSystemName	GreyNoise	Static	Identifies the source system
Name	event_type	Dynamic	Type of CVE event
DeviceVendor	GreyNoise	Static	Vendor information
RuleGenerator	GreyNoise-Feed	Static	Static value for consistency
StartTime	timestamp	Dynamic	Time the event was generated
DeviceProduct	GreyNoise-Feed	Static	Product information
EndTime	timestamp	Dynamic	Time the event ended

EventsList	first(1)	Dynamic	List of events
EventProduct	GreyNoise	Static	Product information
EventName	event_type	Dynamic	Name of the event

Mapping for IP Classification Change Webhook

Field	Mapping Value	Value Type	Description
TicketID	ip	Dynamic	Unique identifier for the IP event
SourceSystemName	GreyNoise	Static	Identifies the source system
Name	event_type	Dynamic	Type of IP event
DeviceVendor	GreyNoise	Static	Vendor information
RuleGenerator	GreyNoise-Feed	Static	Static value for consistency
StartTime	timestamp	Dynamic	Time the event was generated
DeviceProduct	GreyNoise-Feed	Static	Product information
EndTime	timestamp	Dynamic	Time the event ended
Priority	new_state.classification	Dynamic	New classification state
EventsList	first(1)	Dynamic	List of events

EventProduct	GreyNoise	Static	Product information
EventName	event_type	Dynamic	Name of the event

2.3. Supported Webhook Schemas

CVE Status Change

```
{
  "cve": "CVE-2022-31718",
  "event_type": "cve-status-change",
  "metadata": {},
  "new_state": {
    "activity_seen": false,
    "benign_ip_count_10d": 0,
    "benign_ip_count_1d": 0,
    "benign_ip_count_30d": 0,
    "threat_ip_count_10d": 1,
    "threat_ip_count_1d": 1,
    "threat_ip_count_30d": 1
  },
  "old_state": {
    "activity_seen": true,
    "benign_ip_count_10d": 0,
    "benign_ip_count_1d": 0,
    "benign_ip_count_30d": 0,
    "threat_ip_count_10d": 0,
    "threat_ip_count_1d": 0,
    "threat_ip_count_30d": 0
  },
  "timestamp": "2025-08-11T10:30:16.972504375Z"
}
```

CVE Activity Spike

```
{
```

```
"ip": "47.239.198.223",
"tag": "Palo Alto Networks Login Scanner",
"event_type": "New IP Activity",
"event": "added",
"timestamp": "2025-04-30T08:10:00Z"
}
```

IP Classification Change

```
{
  "event_type": "ip-classification-change",
  "ip": "86.57.2.53",
  "new_state": {"classification": "malicious"},
  "old_state": {"classification": "unknown"},
  "timestamp": "2025-08-11T10:42:39Z",
  "workspace_id": "e4a5be2e-1be0-4105-a5e2-51e6a5525fa0"
}
```

Ontology Mapping

Ontology mapping in Google SecOps SOAR enables automatic entity extraction and relationship building from GreyNoise Webhook and Connector data. This enhances threat intelligence correlation, investigation efficiency, and automated response capabilities.

Import Ontology Manually

- Navigate to **Settings -> SOAR Settings -> Ontology**
- Open **Ontology Status**. Use the Import option available on the right-hand side in the middle of the page.
- Select the downloaded [Ontology zip](#). It will be imported.

Note: Ontology will be bundled as part of the integration once it gets published officially.

Ontology Mapping Table

Entity Field	Source Field(s)
SourceAddress	ip
CVE	cve

Limitations

- For **Execute GNQL Query** action, keep max result value under 1,000 to avoid exceeding Google SecOps action payload limitation of **28 MB**.
- Once the indicator is ingested into Google SecOps and an alert is created, it cannot be updated in the next polling interval due to platform limitations in Google SecOps.
- Currently we have temporarily mapped **Alert Priority** to the **classification** field for webhooks, even though Priority is an enum field and the direct mapping will not produce the expected results. The webhook expression builder in Google SecOps does not support nested if-else logic for mapping multiple classification values to priority levels (e.g., mapping “malicious → CRITICAL”, “suspicious → HIGH”, etc.), as discussed in the [community](#). This limitation means priority determination must be handled via playbooks until more flexible mapping is supported in webhook.

Known Behaviors

- We observed that, at times, HTML content (including styles) does not render as expected in the Case Wall, even though the same content renders correctly in the Entity Insight (Overview tab).
- The script timeout might not work as expected. It has been observed that when specifying the timeout to 10 seconds, the action script would timeout after around 39 seconds. The platform adds ~29 seconds of timeout. This behavior differs for every SecOps SOAR instance.

Reference: [Solved: Facing inconsistencies in Script Timeout for Action... - Google Cloud Community](#)

- The connector execution is not guaranteed to occur exactly at the configured Run Every interval, it will be triggered once at some point during the specified interval window due to platform scheduling behavior.
- Configuring Max Results to a large value for the connector can significantly increase data fetch and processing time. In such cases, the connector execution may exceed the allowed runtime and time out before completion. This behavior depends on the volume of data being retrieved by the connector.

Troubleshooting

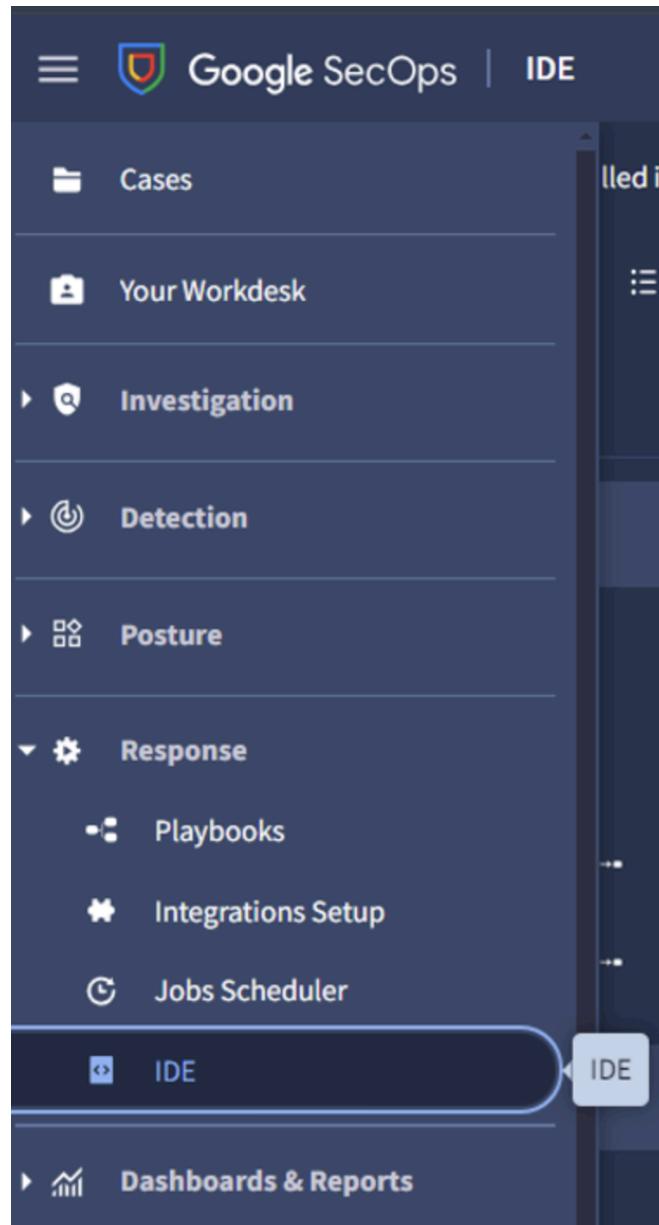

Case 1: PythonProcess Has timed out.

The screenshot shows a troubleshooting interface with the following details:

- Environment: Default Environment_1
- Message: PythonProcess Has timed out. (Max 39 seconds)
- Scope: All entities
- Result: The step did not return any results.

Solution :

1. Increase the script timeout from the Timeout Configuration of an action
 - a. From the Sidebar, navigate to **Response > IDE**

- b. Search for the action script and select it. You will be able to see the codebase of the action, and on the right side, there should be an input field named Timeout Configuration under the details tab. Update the value of Script Timeout based on your requirement, and Save the action

The screenshot shows the GreyNoise API interface. At the top, there's a header with a gear icon, 'Execute GNQL Query' button, 'GreyNoise' logo, 'Created by:' dropdown, and a 'Save' button. Below the header is a text area titled 'Editor (Python V3.11)' containing the following Python code:

```

1  from __future__ import annotations
2  import json
3
4  from greynoise.exceptions import RateLimitError, RequestFailure
5  from ScriptResult import EXECUTION_STATE_COMPLETED, EXECUTION_STATE_FAILED
6  from SiemplifyAction import SiemplifyAction
7  from SiemplifyUtils import output_handler
8  from api_manager import APIManager
9  from constants import (
10      EXECUTE_GNQL_QUERY_SCRIPT_NAME,
11      RESULT_VALUE_TRUE,
12      RESULT_VALUE_FALSE,
13      COMMON_ACTION_ERROR_MESSAGE,
14      GNQL_PAGE_SIZE,
15      MAX_RESULT_SIZE,
16  )
17  from utils import get_integration_params, validate_integer_param
18  from greynoise_exceptions import InvalidIntegerException
19
20
21  def process_gnql_query(greynoise_manager, query, max_results, exclude_raw, quick, siemplify):
22      """
23          Process GNQL query and return results, automatically paginating
24          through all pages.
25
26      Args:
27          greynoise_manager (APIManager): APIManager instance.
28          query (str): GNQL query string.
29          max_results (int): Maximum number of results to fetch.

```

To the right of the editor are three tabs: 'Details', 'Testing', and 'Debug Output'. The 'Details' tab is selected. It contains the following configuration:

- Output Name:** ScriptResult
- Include JSON Result:**
- Timeout configuration:** Script Timeout: 20 Minutes, 0 Seconds
- Default Return Value:**

Below these settings is a table titled 'Parameters' with the following columns: PARAMET..., TYPE, DEFAULT..., MANDAT..., and DESCRIPT... . The table contains three rows:

PARAMET...	TYPE	DEFAULT...	MANDAT...	DESCRIP...
GNQL Q...	String	last_se...	✓	(i)
Max Res...	String			(i)
Quick	Boolean	False		(i)
Exclude...	Boolean	True		(i)

- Another way to increase the execution speed of the action is to tweak the query parameters of the API call by reducing the time frame to search and retrieve only filtered subsets instead of all results

Case 2: Unknown error running Action.

The screenshot shows the 'Script Result' page. The title is 'Script Result' and the status is 'is_success'. Below the title, the text 'Output message' is followed by the error message: 'Unknown error running ActiveDirectory_Ping. Details: Status(StatusCode="Unavailable", Detail="no healthy upstream")'

Solution:

The "no healthy upstream" error indicates an internal system issue. The most common cause is that all backend servers are currently unavailable or unresponsive. To resolve this problem, you should contact your system administrator for assistance.
